# **ORGANIC CHEMISTRY BASED ON FUNCTIONAL GROUPS -II**

# ALDEHYDES AND KETONES

Aldehydes and ketones are compounds containing a carbonyl (C = O) functional group.

The general formula of aldehyde is R-CHO and that of ketone is R-CO-R'. Where R and R' are alkyl or aryl groups.

#### Structure

The carbon atom of the carbonyl group is  $sp^2$  hydridised. Therefore it forms 3 sigma bonds at 120° to each other. The 4<sup>th</sup> unhybridised 'p' orbital overlaps with a 'p' orbital of oxygen to form a  $\pi$  bond. The carbonyl carbon atom and the three atoms bonded to it lie in one plane. The  $\pi$  electron cloud is above and below this plane.

# Polarity of carbonyl group

The carbonyl group is polar in nature. This is due to the higher electro-negativity of oxygen relative to carbon. Hence the carbonyl carbon is an electrophilic (Lewis acid) and carbonyl oxygen is nucleophilic (Lewis base) centre.

The high polarity of carbonyl group is also explained on the basis of the resonance involving neutral and dipolar structures.

$$c = 0 \leftrightarrow c - \bar{o}$$

The polar nature of aldehydes and ketones is confirmed by their large dipole moments. [Acetaldehyde (2.72D) and acetone (2.88D)]. The dipole moments of aldehydes and ketones are higher than that of ethers.[Diethyl ether (1.18D)]

### **Nomenclature**

The trivial names (common names) of aldehydes are derived from the names of corresponding acids by replacing "*ic acid*" by "*aldehyde*". The carbon atoms are indicated by Greek letters  $\alpha$ ,  $\beta$ ,  $\gamma$  etc .

$$\begin{array}{c} \text{CH}_3 - \text{CH}_2 - \text{CH} - \text{CH}_2 - \text{CHO} \\ \text{I} \\ \text{CH}_3 \end{array} \qquad \begin{array}{c} \beta \text{ - Methyl valeraldehyde (Common Name)} \\ 3 - \text{methyl pentanal (IUPAC Name)} \end{array}$$

In IUPAC system, an aldehyde has the ending '**al**'. The longest carbon chain including the – CHO group is selected as the parent hydrocarbon.

Compound	Trivial names	IUPAC names
H - CHO	Formaldehyde	Methanal
CH₃ – CHO	Acetaldehyde	Ethanal
CH <sub>3</sub> – CH <sub>2</sub> – CHO	Propionaldehyde	Propanal
CH <sub>3</sub> – CH <sub>2</sub> – CH <sub>2</sub> – CHO	n-Butyraldehyde	Butanal
CH <sub>3</sub> — CH — CH <sub>3</sub>	Iso-Butyraldehyde	2-methyl propanal
l CH₃		
CH <sub>3</sub> CHO	$\gamma$ - methyl cyclohexane carbaldehyde	3-methyl cyclohexane carbaldehyde
СНО	Benzaldehyde	Benzaldehyde
CHO NO <sub>2</sub>	p-Nitrobenzaldehyde	4-Nitrobenzaldehyde
CH <sub>3</sub> CHO	o-Tolualdehyde	2-Methyl benzaldehyde
CH <sub>2</sub> – CHO	Phenyl acetaldehyde	2-phenyl ethanal
CH <sub>3</sub> – CH = CH – CHO	Crotonaldehyde	But-2-enal
сно	Phthaladehyde	Benzene-1,2-dicarbaldehyde
CH <sub>2</sub> = CH – CHO	Acrolein	Prop-2-enal

Vanillin (from vanilla beans), salicyladehyde (from meadow sweet) and cinnamaldehyde (from cinnamon)have very pleasant fragrances.

They are used in many food products and pharmaceuticals to add flavours.

In common system ketones are named by using the names of alkyl groups attached to carbonyl group followed by the word '*ketone*' Eg:  $CH_3 CO C_2H_5$  Ethyl methyl ketone.

In IUPAC system the longest carbon chain containing the 'keto' group is selected as the parent hydrocarbon. The name of the ketone is obtained by replacing 'e' of the alkane by 'one'. The position of the keto group is indicated by a number.

The common name and IUPAC names of the some ketones are given in the table.

Compound	Common name	IUPAC name
CH <sub>3</sub> CO CH <sub>3</sub>	Acetone	Propanone
CH <sub>3</sub> CO C <sub>2</sub> H <sub>5</sub>	Ethyl methyl ketone	Butan-2-one
CH <sub>3</sub> CO CH CH <sub>3</sub>   CH <sub>3</sub>	Methylisopropyl ketone	3-methylbutane-2-one
CH <sub>3</sub> CH CO CH CH <sub>3</sub>     CH <sub>3</sub> CH <sub>3</sub>	Di-isopropyl ketone	2,4-Dimethylpentan-3-one
© C − CH <sub>3</sub> 0	Methyl phenyl ketone	Acetophenone
	Diphenyl ketone	Benzophenone
0	lpha -methyl cyclohexanone	2-methyl cyclohexanone
CH₃ CO CO CH₃	Diacetyl	Butane-2,3-dione
$(CH_3)_2C = CH - CO - CH_3$	Mesityl oxide	4-methyl pent-3-en-2-one
O     C - CH <sub>2</sub> - CH <sub>3</sub>	Ethyl phenyl ketone (Propiophenone)	1- Phenyl propan-1-one

# **METHODS OF PREPARATION**

# (1) FROM ALCOHOLS

(a) <u>By oxidation</u> – Aldehydes and ketones can be prepared by the oxidation of primary and secondary alcohols respectively. The commonly used oxidizing agents are K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and KMnO<sub>4</sub> or CrO<sub>3</sub>. However these are strong oxidizing agents and further oxidize aldehydes to carboxylic acids.

CH<sub>3</sub> CH<sub>2</sub> OH 
$$\xrightarrow{[O]}$$
 CH<sub>3</sub> CHO + H<sub>2</sub>O

CH<sub>3</sub> CH CH<sub>3</sub>  $\xrightarrow{[O]}$  CH<sub>3</sub> CO CH<sub>3</sub> + H<sub>2</sub>O

OH

# (b) By using Pyridinium chloro chromate(PCC) [C<sub>5</sub> H<sub>5</sub> NH<sup>+</sup> CrO<sub>3</sub> Cl<sup>-</sup>]

PCC is a milder oxidizing agent. It oxidizes primary alcohols to aldehydes and secondary alcohols to ketones in dichloromethane solvent. <u>The aldehydes are not further oxidized to carboxylic acids</u>. The carbon - carbon double bonds also remain unaffected.

$$\begin{array}{ccc} \text{CH}_3\,\text{CH}_2\,\text{OH} & \xrightarrow{\text{PCC}} & \text{CH}_3\,\text{CHO} \\ \hline \\ & & \text{OH} & \xrightarrow{\text{PCC}} & & \text{O} \\ \hline \\ & & & \text{CH}_3\text{CI}_2 & & \text{O} \\ \end{array}$$

# (c) By dehydrogenation (By using Ag or Cu)

Aldehydes and ketones can also be prepared by passing vapours of alcohols over heated copper gauze at 573 K. Primary alcohols give aldehydes while secondary alcohols give ketones.

$$\begin{array}{ccc} \text{CH}_3\,\text{CH}_2\,\text{OH} & \xrightarrow{\text{Cu}} & \text{CH}_3\,\text{CHO} + \text{H}_2 \\ \\ \text{CH}_3\,& \text{CH} & \text{CH}_3 & \xrightarrow{\text{Cu}} & \text{CH}_3\,\text{CO}\,\text{CH}_3 + \text{H}_2 \\ \\ \text{OH} & & \text{OH} & & \\ \end{array}$$

#### From acid chlorides [Rosenmund reduction] (2)

Aldehydes are prepared from acid chloride by reaction with hydrogen in the presence of palladium catalyst spread over barium sulphate. The catalyst is partially deactivated by addition of sulphur or quinoline. This is to prevent further reduction of aldehydes to alcohols. This reaction is called Rosenmund's reaction.

$$\begin{array}{cccc} CH_3-CO-CI+H_2 & \xrightarrow{Pd,BaSO_4} & CH_3CHO & + & HCI \\ & S & & Acetaldehy de \end{array}$$
 
$$C_6H_5-CO-CI+H_2 & \xrightarrow{Pd,BaSO_4} & C_6H_5 CHO & + & HCI \\ & S & & Benzoyl chloride & S & Benzaldehy de \end{array}$$

#### By Ozonolysis of alkenes (3)

Alkenes react with ozone to form ozonides which on decomposition with water in the presence of zinc dust give aldehydes and ketones. This process is called **ozonolysis** 

$$CH_{3} - CH = CH - CH_{3} \xrightarrow{O_{3}} CH_{3} - CH - O - CH - CH_{3} \xrightarrow{H_{2}O/Zn} 2CH_{3} - CHO + H_{2}O_{2}$$

$$O = O$$

$$CH_{3} - CH = C \xrightarrow{CH_{3}} \xrightarrow{O_{3}} CH_{3} - CH - O - C \xrightarrow{CH_{3}} \xrightarrow{H_{2}O/Zn} CH_{3} - CHO + CH_{3} - CO - CH_{3}$$

$$CH_{3} - CH = C \xrightarrow{CH_{3}} \xrightarrow{O_{3}} CH_{3} - CH - O - C \xrightarrow{CH_{3}} \xrightarrow{H_{2}O/Zn} CH_{3} - CHO + CH_{3} - CO - CH_{3}$$

#### (4) From Alkynes

Aldehydes and ketones can be prepared by the hydration of alkynes

Eg: 
$$CH_3 \equiv CH + H_2O \xrightarrow{H_2SO_4} CH_3 - CHO$$

$$CH \equiv CH + H - OH \xrightarrow{H_2SO_4} CH_3 - CHO$$

$$CH_3 = CH + H - OH \xrightarrow{H_2SO_4} CH_3 - CHO$$

$$CH_3 - C \equiv CH + H - OH \xrightarrow{H_2SO_4} CH_3 - C = CH_2 \xrightarrow{Isomerisat ion} CH_3 - C - CH_3$$

$$CH_3 - C \equiv CH + H - OH \xrightarrow{H_2SO_4} CH_3 - C = CH_2 \xrightarrow{Isomerisat ion} CH_3 - C - CH_3$$

$$O - H$$

$$O$$
Propanone

#### (5) From Nitriles and esters

Nitriles are reduced to corresponding imine with stannous chloride in the presence of hydrochloric acid, which on hydrolysis give corresponding aldehyde.

$$RCN + SnCl_2 + HCI \rightarrow RCH = NH \xrightarrow{H_2O^+} RCHO$$

This reaction is called **Stephen reaction**.

Alternatively, nitriles are selectively reduced by diisobutylaluminium hydride, (DIBAL - H) to imines followed by hydrolysis to aldehydes:

$$\begin{array}{c} RCN \xrightarrow{\phantom{a} 1.AlH(i-Bu)_2 \phantom{a}} R-CHO \\ \hline CH_3-CH=CH-CH_2\ CH_2-CN \xrightarrow{\phantom{a} 1.AlH(i-Bu)_2 \phantom{a}} CH_3-CH=CH-CH_2CH_2-CHO \end{array}$$

Similarly, esters are also reduced to aldehydes with DIBAL – H.

$$CH_3(CH_2)_9 - C - OC_2 H_5 \xrightarrow{1.DIBAL - H} CH_3(CH_2)_9 - C - H_3(CH_2)_9 - C - H_$$

# **Preparation of Aromatic aldehydes and Ketones**

Oxidation of toluene and its derivatives using strong oxidizing agents give benzoic acid. But under special conditions toluene can be oxidized to benzaldehyde.

# (i) Using CrO<sub>3</sub>:

Aromatic aldehydes are obtained by the oxidation of side chain in an aromatic ring using chromium trioxide (CrO<sub>3</sub>) in acetic anhydride. Acetic anhydride converts the aldehydes formed into non oxidisable product [**benzylidine diacetate**] and prevents further oxidation into acids. It is then hydrolysed by alkali to give aldehyde.

### (ii) Etard's reaction

When toluene is oxidized with chromyl chloride, benzaldehyde is formed. This reaction is called Etard's reaction.

# (iii) By side chain chlorination followed by hydrolysis

# (iv) By Gatterman - Koch reaction

Benzene or its derivatives when treated with CO + HCl in presence of anhydrous aluminium chloride or cuprous chloride give benzaldehyde or its derivatives

# Preparation of ketones

### (1) From acid chlorides

Treatment of acid chlorides with dialkyl cadmium give ketones. The dialkyl cadmium is prepared by the reaction of cadmium chloride with Grignard reagent.

## (2) From nitriles

Treatment of nitrile with Grignard reagent followed by hydrolysis give ketones.

$$CH_{3}-CH_{2}-C\equiv N+C_{6}\ H_{5}\ Mg\ Br \xrightarrow{Ether} CH_{3}-CH_{2}-C \xrightarrow{N}\ Mg\ Br \xrightarrow{H_{3}O^{+}} C_{2}\ H_{5}-C-C_{6}\ H_{5}$$

# (3) By Friedel Craft's reaction

Aromatic ketones can be prepared by treating an aromatic hydrocarbon with an acid chloride in presence of anhydrous AlCl<sub>3</sub>.

$$\begin{array}{c}
CO - CH_3 \\
\hline
O + CH_3 - CO - CI \xrightarrow{Al Cl_3} & + HCI
\end{array}$$
Acetophenone

This reaction is called Friedel Craft's acylation. This reaction is an example of electrophilic substitution reaction.

# Physical properties

Most of the aldehydes are liquids of room temperature (except formaldehyde which is a gas). The lower aldehydes have a sharp pungent smell.

Lower ketones are colourless liquids but higher members are colourless solids. Ketones have a pleasant smell.

## **Boiling point:**

Aldehydes and ketones have higher boiling point than hydrocarbons of comparable molecular masses. This is because aldehydes and ketones contain polar carbonyl groups and therefore they have intermolecular dipole-dipole interactions.

This dipole-dipole interaction is weaker than intermolecular H-bonding in alcohols. Therefore B.P of aldehydes and ketones are relatively lower than the alcohols of comparable molecular masses.

Eg: 
$$CH_3-CH_2-CHO$$
  $CH_3-CH_2-CH_2-OH$   $CH_3-CH_2-CH_3-CH_2-CH_3$   $M.W = 58 \ B.P = 322 \ K$   $M.W = 60, \ B.P = 371 \ K$   $M.W = 58 \ BP = 309 K$ 

#### Solubility:

The lower members of aldehydes and ketones are soluble in H<sub>2</sub>O. It is due to their capability of forming hydrogen bonds with water. As the size of the alkyl group increases, the solubility in water decreases.

$$\begin{array}{c}
R \\
C = 0 & \text{H} & \text{H} & \text{H} & \text{H} \\
R'
\end{array}$$

Q. Arrange the following compounds in the increasing order of their boiling points.

# **CHEMICAL PROPERTIES:**

Aldehydes and ketones are highly reactive compounds. Most of the reaction of aldehydes and ketones are similar due to the presence of common carbonyl group.

### **Nucleophilic addition reactions**

The carbonyl group is polarized due to the higher electronegativity of oxygen than carbon. Therefore aldehydes and ketones undergo attack by nucleophilies at the carbonyl carbon.

$$c = 0$$

### Mechanism

The nucleophile (Nu) will attack the carbonyl carbon from above or below the plane of the carbonyl group to form the C-Nu bond. It is accompanied by heterolytic cleavage of the carbon-oxygen pi bond. The pi bond electrons are transferred to the oxygen atom. During this process the hybridization of carbonyl carbon changes from  $sp^2$  to  $sp^3$ . The negatively charged oxygen then captures a proton from the medium to give the final product.

## Reactivity

Aldehydes are more reactive than ketones towards nucleophilic reactions. This is due to the electron-repelling (+ I) inductive effect of alkyl groups. The presence of two alkyl groups at the carbonyl carbon atom in ketones decreases the positive charge over it. Therefore the tendency of attack by a nucleophile decreases. In ketones, the presence of bulky alkyl groups also hinders the approach of the nucleophile to the carbonyl carbon. This factor is called the steric factor.

Benzaldehyde is less reactive than aliphatic aldehydes. This is due to the electron releasing resonance effect of benzene ring.

Due to this electron releasing resonance effect (+R effect) the magnitude of positive charge decreases and becomes less susceptible to the nucleophilic attack.

- Q. Arrange the following compounds in the increasing order of reactivity
  - 1. Ethanal, Propanal, Propanone, Butanone
  - 2. Benzaldehyde, p-Tolualdehyde, p-Nitrobenzaldehyde, Acetophenone

#### Ans:

- 1. Butanone < Propanone < Propanal < Ethanal.
- 2. Acetophenone < p-Tolualdehyde < Benzaldehyde < p-Nitrobenzaldehyde

# I. Addition Reactions

### (a) Addition of hydrogen cyanide:

Both aldehydes and ketones form addition products called *cyanohydrins* with HCN. This reaction is slow with pure HCN. Therefore it is catalysed by a base (HCN + NaOH  $\rightarrow$  CN<sup>-</sup> + H<sub>2</sub>O)

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - CN \xrightarrow{H^{+}} CH_{3}-C - CN$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - O \xrightarrow{H^{+}} CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - O \xrightarrow{H^{+}} CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - O \xrightarrow{H^{+}} CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

$$CH_{3}-C = O + C\overline{N} \longrightarrow CH_{3}-C - OH$$

# (b) Addition of sodium bisulphite

Sodium hydrogen sulphite adds to carbonyl compounds to form crystalline addition products. Most of the aldehydes and a few ketones like methyl ketones form bisulphite addition products.

CH<sub>3</sub>—C = O + NaHSO<sub>3</sub> 
$$\longrightarrow$$
 CH<sub>3</sub>—C —  $\stackrel{+}{O}$  Na  $\stackrel{Proton transfer}{\downarrow}$  CH<sub>3</sub>—C — OH  $\stackrel{+}{SO_3}$ Na  $\stackrel{+}{SO_3}$ Na  $\stackrel{+}{SO_3}$ Na Acetaldehyde bisulpha addition product

Acetaldehyde bisulphate addition product

The bisulphate addition compound can be converted back into aldehydes and ketones by treating it with dil acid or alkali. Hence this reaction can be used for the separation and purification of aldehydes and ketones.

CH<sub>3</sub>—C—OH 
$$\xrightarrow{\text{HCI}}$$
 CH<sub>3</sub>—CHO + SO<sub>2</sub> + NaCI + H<sub>2</sub>O  
|  
| SO<sub>3</sub>Na

# (c) Addition of Grignard reagent:

Aldehydes and ketones form addition compounds with Grignard reagent which on hydrolysis give alcohols. Here formaldehyde form primary alcohol, all other aldehydes form 2° alcohols and ketones form 3° alcohols

H - C - H + CH<sub>3</sub> - Mg Br 
$$\longrightarrow$$
 H - C - O Mg Br  $\xrightarrow{H_2O}$  CH<sub>3</sub> - CH<sub>2</sub> - OH + Mg OH CH<sub>3</sub> - C - O Mg Br  $\xrightarrow{H_2O}$  CH<sub>3</sub> - CH - OH + Mg OH CH<sub>3</sub> - C - O Mg Br  $\xrightarrow{H_2O}$  CH<sub>3</sub> - CH - OH + Mg OH CH<sub>3</sub> - C - O Mg Br  $\xrightarrow{H_2O}$  CH<sub>3</sub> - CH - OH + Mg OH CH<sub>3</sub> - C - O Mg Br  $\xrightarrow{H_2O}$  CH<sub>3</sub> - CH - OH + Mg OH

# (d) Addition of alcohols

Aldehydes react with monohydric alcohols in the presence of dry HCl gas to form gem-dialkoxy compounds called acetals. In this reaction addition of one molecule of alcohol results in the formation of a hemiacetal. It is an unstable compound and reacts with another alcohol molecule to form stable acetal.

$$R - C \longrightarrow + R' - OH \xrightarrow{Dry \ HCl \ gas} \qquad R - C - OH \longrightarrow OR'$$

$$Hemi \ acetal$$

$$H \longrightarrow C \longrightarrow OH + R' - OH \xrightarrow{Dry \ HCl \ gas} \qquad R - C - OR' + H_2O \longrightarrow OR'$$

$$OR' \longrightarrow OR'$$

$$Acetal$$

Ketones usually do not react with monohydric alcohols. But ketones react with ethylene glycol to form cyclic products known as ethylene glycol ketals

$$\begin{array}{c} R \\ C = O \\ R' \end{array} + \begin{array}{c} CH_2 - OH \\ CH_2 - OH \end{array} \xrightarrow{\begin{array}{c} HCI \text{ gas} \\ \hline \text{dil } HCI \end{array}} \begin{array}{c} R \\ C \\ \hline R' \end{array} O \xrightarrow{CH_2} CH_2 \\ + H_2O \\ \hline \text{Ethylene glycol ketal} \end{array}$$

# (e) Addition of ammonia and its derivatives

Aldehydes and ketones react with ammonia and its derivatives to give compounds containing >C=N-Z group. These are crystalline compounds and are used for the characterization of aldehydes and ketones.

$$\begin{array}{c|c}
 & NZ \\
 & \parallel \\
 & R - C - R' + H_2N - Z \longrightarrow R - C - R' + H_2O
\end{array}$$

# (1) With ammonia: Aldehydes react with ammonia to imines

$$CH_3 - CHO + NH_3 \quad \rightarrow CH_3 - CH = NH$$
 Accetalde min e

# (2) With amine (R- NH<sub>2</sub>)

$$CH_3-CHO+R-NH_2 \ \, \rightarrow \ \ \, CH_3-CH=N-R \\ \text{Substitute d imin e (Schiff 'sbase)}$$

# (3) With hydroxylamine:

Aldehydes and ketones react with hydroxylamines to form oximes.

$$CH_3 - CHO + H_2N - OH \xrightarrow{H^+} CH_3 - C = N - OH + H_2O$$

#### Ethanal oxime

## (4) With hydrazine:

They produce the corresponding hydorazones

Acetone hydrazone

### (5) With Phenyl hydrazine: They produce the respective phenyl hydrazones

$$CH_{3}-CHO+H_{2}N-NH-C_{6}H_{5} \rightarrow CH_{3}-CH=N-NH-C_{6}H_{5}+H_{2}O$$

$$Accetaldehy de phenyl hydrazone$$

$$CH_{3}-CO-CH_{3}+H_{2}N-NH-C_{6}H_{5} \longrightarrow CH_{3}-CH=N-NH-C_{6}H_{5}+H_{2}O$$

$$CH_{3}-CO-CH_{3}+H_{2}N-NH-C_{6}H_{5} \longrightarrow CH_{3}-CH=N-NH-C_{6}H_{5}+H_{2}O$$

$$CH_{3}-CO-CH_{3}+H_{2}N-NH-C_{6}H_{5}+H_{2}O$$

Acetone phenyl hydrazine

# (6) With 2,4-dinitro phenyl hydrazine

$$R - CHO + H_2N - NH - \bigcirc NO_2$$

$$R - CH = N - NH - \bigcirc NO_2$$

$$R - CH = N - NH - \bigcirc NO_2$$

$$R - CH = N - NH - \bigcirc NO_2$$

$$R - CH = N - NH - \bigcirc NO_2$$

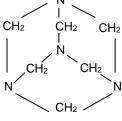

$$R - CH = N - NH - \bigcirc NO_2$$

# (7) <u>With semicarbazide:</u> They give the respective semicarbazones.

$$\text{CH}_3-\text{CHO}+\text{H}_2\text{N}-\text{NH}-\text{CO}-\text{NH}_2 \to \text{CH}_3-\text{CH}=\text{N}-\text{NH}-\text{CO}-\text{NH}_2+\text{H}_2\text{O}$$
 Semicarbaz ide Acetaldehy de semicarbaz one

Formaldehyde reacts with ammonia to form hexamethylene tetraamine. It is known as urotropine.

$$\begin{array}{c} \textrm{6 HCHO + 4NH}_{3} \rightarrow \textrm{(CH}_{2})_{6}\textrm{N}_{4}\textrm{+}\,\textrm{6H}_{2}\textrm{O} \\ \textrm{Urotopine} \end{array}$$

Urotropine

Controlled nitration of urotropine produces an explosive *RDX* (*Research and development explosive*)

### **II Oxidation**

Aldehydes are easily oxidized to carboxylic acids when treated with common oxidizing agents like nitric acid ,  $KMnO_4$  and  $K_2Cr_2O_7$ . They are even oxidized by mild oxidizing agents such as  $Ag^+$  and  $Cu^{2+}$  ions in alkaline medium.

$$R - CHO \xrightarrow{[O]} R - COOH$$

Ketones are not oxidized easily. Under vigorous conditions, the cleavage of carbon-carbon bond take place yielding a mixture of acids having less number of carbon atoms.

$$R-CH_2-CO-CH_2-R' \xrightarrow{[O]} R-COOH + R'-CH_2-COOH$$

The easy oxidation of aldehyde is due to the presence of a hydrogen atom on the carbonyl group which can be converted into - OH group. Ketones do not contain any hydrogen attached to the >C = O group. Hence they are resistant to oxidation.

In the case of unsymmetrical ketones, the cleavage occurs in such a way that keto group stays with the smaller alkyl group. This is known as *Popoff's rule*.

Eg: 
$$CH_3 - CH_2 - CH_2 - CO - CH_3 \rightarrow CH_3 - CH_2 - COOH + CH_3 - COOH$$

Since <u>aldehydes</u> are readily oxidized they behave as good reducing agents

# (i) Tollen's test

**Tollen's reagent** is ammoniacal silver nitrate solution. Tollen's reagent contains  $Ag^+$  ions complexed with ammonia,  $Ag(NH_3)_2^+$ , which prevents precipitation of silver oxide in basic solution. In the oxidation of aldehydes with Tollen's reagent, silver ions are reduced to metallic silver and a silver mirror is produced on the inner sides of the test tube. Hence this test is known as silver mirror test.

$$R - CHO + 2 Ag (NH_3)^{+}_2 + 3OH^{-} \rightarrow R - COO^{-} + 2 Ag + 2H_2O + 4 NH_3$$

# (ii) Fehling's test

Fehling solution is an alkaline solution of  $CuSO_4$  containing <u>sodium potassium tartrate</u> (*Rochelle salt*). Fehling's solution comprise of two solutions. *Solution A*  $\rightarrow$  Aqueous  $CuSO_4$ . *Solution B*  $\rightarrow$  Alkaline sodium potassium tartarate. These two solutions are mixed in equal amounts before the test.

Aldehydes reduce copper (II) to Cu(I) and a red precipitate of cuprous oxide (Cu<sub>2</sub>O) is formed.

$$\label{eq:rate} \text{R}-\text{CHO} \ + \ 2 \ \text{Cu}^{2+} + 5 \text{OH}^- \quad \rightarrow \ \text{R}-\text{COO}^- \ + \ \text{Cu}_2 \text{O} \ + 3 \text{H}_2 \text{O}$$

#### (iii) Benedict's test

Benedict's solution is alkaline solution of cupric [Cu(II)] ion complexed with citrate ions. The reaction is same as that of Fehling's solution.

$${\rm R-CHO} \ + \ 2 \ {\rm Cu^{2+}} + 5 {\rm OH^{-}} \rightarrow \ {\rm R-COO^{-}} \ + \ {\rm Cu_{2}O} \ + \ 3 {\rm H}_{2}{\rm O}$$

Ketones do not give the above tests. Therefore the above tests are used to distinguish between aldehydes and ketones

#### 3. Reduction

On reduction using reducing agents like LiAlH<sub>4</sub>, sodium borohydride (NaBH<sub>4</sub>) or H<sub>2</sub> in the presence of Ni, an aldehyde gives a primary alcohol while a ketone gives a secondary alcohol.

$$R - CHO \xrightarrow{LiAlH_4} R - CH_2 - OH \quad (1^0 \text{ alcohol})$$

$$R - CO - R \xrightarrow{LiAlH_4} R - CH - R \quad (2^0 \text{ alcohol})$$

$$OH$$

# Clemmensen's Reduction

Aldehydes and ketones on reduction with zinc amalgam and con.HCl, give the corresponding hydrocarbons. This reaction is known as *Clemmensen's reduction*.

$$CH_3 - CHO + 4(H) \xrightarrow{\quad Zn/Hg \quad } CH_3 - CH_3 + H_2O$$

$$CH_3 - CHO + CH_3 + 4(H) \xrightarrow{Zn/Hg} CH_3 - CH_2 - CH_3 + H_2O$$

#### Wolf-kishner Reduction

Aldehydes and ketones can be converted into corresponding hydrocarbons by wolf-kishner reduction. In this method, aldehyde and ketone is heated with hydrazine and KOH in ethylene glycol as solvent.

$$CH_3-CHO+ \ H_2N-NH_2 \ \rightarrow \ CH_3-CH=N-NH_2 \ \xrightarrow{\ KOH/453-473K \ } \ CH_3-CH_3+N_2$$

$$CH_{3}-CO-CH_{3}+H_{2}N-NH_{2} \rightarrow CH_{3}-CH=N-NH_{2} \xrightarrow{KOH/453-473\,K} CH_{3}-CH_{2}-CH_{3}+N_{2} \\ | \\ CH_{3}$$

# Acidity of α -hydrogen of aldehydes and ketones

The  $\,\alpha$ -hydrogen of aldehydes and ketones are acidic in nature. The acidity of hydrogen is due to the strong electron withdrawing effect of the carbonyl group and resonance stabilization of the conjugate base.

# 5. Aldol Condensation

Aldehydes and Ketones <u>having atleast one  $\alpha$ -hydrogen atom</u>, when treated with dil alkali undergo condensation reaction to form  $\beta$ -hydroxy aldehydes or  $\beta$ - hydroxy ketones. They undergo dehydration very easily to form unsaturated carbonyl compounds. This reaction is known as *aldol condensation*.

$$\begin{array}{c} \text{CH}_3 - \text{C} = \text{O} + \text{CH}_3 - \text{CHO} \xrightarrow{\text{OH}^-} \text{CH}_3 - \text{CH} - \text{CH}_2 - \text{CHO} \xrightarrow{\text{heat}} \text{CH}_3 - \text{CH} = \text{CH} - \text{CHO} \\ \text{I} & \text{Crotonaldehyde} \\ \text{OH} & \text{OH} \end{array}$$

$$2CH_3 - \underset{O}{C} - CH_3 \xrightarrow{OH^-} CH_3 - \underset{I}{C} - CH_2 - CO - CH_3 \xrightarrow{\Delta} CH_3 - \underset{-H_2}{C} = CH - CO - CH_3 \xrightarrow{\Delta} 4 - \text{methyl pent -3-en-2-one}$$

The name aldol condensation is derived from the names of two functional groups-aldehyde and alcohol. But ketones on condensation give ketols.

# **Cross aldol condensation**

Aldol condensation of a mixture of two different aldehydes (or ketones) having  $\alpha$ -hydrogen gives a mixture of four products. Two of the products are made up of the same carbonyl compound and are called **self or simple aldol condensation products**. The other two products are formed between two different carbonyl compounds. These are called **cross aldol condensation products**.

# **Cinnamaldehyde**

Cross aldol condensation between benzaldehyde and acetaldehyde give cinnamaldehyde

CHO
$$CH - CH_2 - CHO$$

$$CH = CH - CHO$$

$$CH = CH - CHO$$

$$Cinnamaldehyde$$

$$(3- phenyl prop-2-enal)$$

# (6) Cannizzaro reaction

On treating with concentrated NaOH or KOH, aldehydes having no  $\alpha$ -hydrogen atoms undergo self-oxidation and reduction reaction to give a mixture of acids and alcohols. Here one molecule of the aldehyde is oxidized to an acid while another molecule is reduced to an alcohol. This reaction is known as *Cannizzaro reaction* 

$$\begin{array}{ccc} 2 \text{ H CHO} & \xrightarrow{\text{NaOH}} & \text{CH}_3 - \text{OH} + \text{HCOONa}^+ \\ & & \text{Methanol} & \text{Sodium formate} \\ \\ 2 \text{ C}_6 \text{H}_5 \text{CHO} & \xrightarrow{\text{NaOH}} & \text{C}_6 \text{H}_5 - \text{CH}_2 \text{OH} + \text{C}_6 \text{H}_5 - \text{COONa}^+ \\ \end{array}$$

Benzaldehyde, formaldehyde, trimethyl acetaldehyde etc undergo Cannizzaro reaction.

# (7) Haloform reaction

Aldehydes and ketones having at least one methyl group linked to the carbonyl group react with sodium hypohalite to give haloform.

$$\begin{array}{ccc} & & & & & O \\ \parallel & & \parallel & & \parallel \\ R-C-CH_3 & \xrightarrow{Na\ OX} & R-C-ONa+CHX_3 & (X=CI,\ Br,\ I) \end{array}$$

This reaction does not affect a carbon – carbon double bond if present in the molecule.

$$CH_{3}-CH=C-C-CH_{3} \xrightarrow{Na \ OCI} CH_{3}-CH=C-C-ONa + CH \ CI_{3}$$

$$CH_{3} CH_{3} CH_{3} O$$

# 8. Electrophilic substitution

The carbonyl group acts as a deactivating group and meta directing. Therefore electrophilic substitutions will take place at meta position.

### **Formalin**

40% solution of formaldehyde (8% methanol and 52% water) is known as formalin. Formalin is a disinfectant and a preservative for biological samples.

# Metaformaldehyde or trioxane.

When formaldehyde is allowed to stand at room temperature, it polymerizes to a trimer called trioxane

CH2

# **Paraformaldehyde**

Polymer of formaldehyde is known as paraformaldehyde.

$$(-CH_2-O-CH_2-O-CH_2-O-CH_2-O)_n$$

# <u>Paraldehyde</u>

A trimer of acetaldehyde is called paraldehyde. Paraldehyde is used in medicine as hypnotic.

## **Metaldehyde**

A tetramer of acetaldehyde is called metaldehyde.

4CH<sub>3</sub>-CHO
$$\xrightarrow{H^+}$$
 CH<sub>3</sub> -CH O Metaldehyde O CH - CH<sub>3</sub>

 $\underline{\text{Wacker's process}}$  Acetaldehyde is also manufactured by passing a mixture ethene and  $O_2$  under pressure into an aqueous solution of palladium chloride and cupric chloride catalysts.

$$CH_2 = CH_2 + H_2O + \frac{1}{2}O_2 \xrightarrow{PdCl_2} CH_3 - CHO + H_2O$$

# Uses of aldehyde

- 1. Formaldehyde is used for the manufacture of formalin which is used for preserving biological specimens
- 2. Formaldehyde is also used in the manufacture of bakelite, urea-formaldehyde glue and other polymers.
- 3. Acetaldehyde is used in the manufacture of acetic acid, ethyl acetate, polymers etc.
- 4. Acetaldehyde is also used for the production of paraldehyde and metaldehyde. Paraldehyde is used as a hypnotic.
- 5. Benzaldehyde is used in the manufacture of perfumes and dyes.
- 6. Acetone and ethyl methyl ketone are common industrial solvents.
- 7. Many aldehydes and ketones are obtained from nature. Vanillin (from vanilla beans), salicylaldehyde (from meadow sweet) and cinnamaldehyde (from cinnamon)etc. These are used as flavouring agents.

# **CARBOXYLIC ACIDS**

Organic compounds containing carboxyl group (-C-OH) are termed *carboxylic acids*. The carboxyl group contains a carbonyl group attached to a hydroxyl group.

Some higher members of aliphatic carboxylic acids (C<sub>12</sub> - C<sub>18</sub>) occur in natural fats as esters. Hence these are also known as fatty acids.

# **Nomenclature**

The trivial names of carboxylic acids are based on their source or origin. Eg: Formic acid – It is obtained from red ants (Latin: Formica means ants).

In IUPAC system, the name of an acid is obtained by replacing the terminal 'e' of the corresponding alkane with "oic acid'.

Formula	Common name	IUPAC name
H – COOH	Formic acid	Methanoic acid
CH₃ – COOH	Acetic acid	Ethanoic acid
CH <sub>3</sub> – CH <sub>2</sub> – COOH	Propionic acid	Propanoic acid
CH <sub>3</sub> – CH <sub>2</sub> – CH <sub>2</sub> – COOH	n-Butyric acid	Butanoic acid
CH <sub>3</sub> —CH—COOH	Isobutyric acid	2-methyl propanoic acid
CH <sub>3</sub> CH <sub>3</sub> —CH <sub>2</sub> —CH—COOH	α -Bromobutyric acid	2-Bromobutanoic acid
Br CH <sub>3</sub> – CH <sub>2</sub> – CH <sub>2</sub> – COOH COOH	n- Valeric acid	Pentanoic acid
$\bigcirc$	Benzoic acid	Benzoic acid
COOH NO <sub>2</sub>	O-nitro benzoic acid	2-nitrobenzoic acid
СООН	p-Toluic acid	4-methyl benzoic acid
CH <sub>3</sub> CH <sub>2</sub> – COOH	Phenyl acetic acid	2-phenyl ethanoic acid
соон	Phthalic acid	Benzene-1,2-dicarboxylic acid

# Polycarboxylic acids

Butane-1,2,4 - tricarboxylic acid

$$\begin{array}{c} CH_2-COOH \\ I \\ HOOC-CH_2-CH-CH_2-COOH \end{array}$$

3-(Carboxy methyl) pentane -1,5-dioic acid

# Structure of carboxyl group

In carboxylic acid, the bonds to the carboxyl carbon lie in one plane. The bond angle is 120°. The carboxyl carbon is less electrophilic due to the possible resonance structures.

# **Methods of Preparation**

# (i) By the oxidation of primary alcohols and aldehydes.

Primary alcohols and aldehydes are readily oxidized to the corresponding carboxylic acids by oxidizing agents like KMnO<sub>4</sub> in acidic, neutral or alkaline medium or K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and CrO<sub>3</sub> in acidic medium.

$$\begin{array}{ccc} CH_3-CH_2-CH_2-OH & \xrightarrow{& KMnO_4/H^+$} & CH_3-CH_2-COOH \\ \\ CH_3-CH_2-CHO & \xrightarrow{& KMnO_4$} & CH_3-CH_2-COOH \\ \end{array}$$

Oxidation with  $K_2Cr_2O_7$  or  $CrO_3$  in acidic media often gives some esters. Therefore oxidation with KMnO<sub>4</sub> in neutral or alkaline medium is preferred.

# (ii) From Alkyl benzenes

Alkyl benzenes on oxidation with alkaline KMnO4 give aromatic acids .

$$\begin{array}{ccc}
CH_3 & COOH \\
\hline
O & -KMnO_4/OH^-
\end{array}$$

The alkyl side chain gets oxidized to -COOH group irrespective of the size of the chain.

$$\begin{array}{ccc}
CH_2 - CH_3 & COOH \\
& & & & \\
\hline
CH_3 & & & \\
CH_3 & & & \\
\hline
COOH & \\
COOH & \\
\hline
COOH & \\
\hline
COOH & \\
\hline
COOH & \\
COOH & \\
\hline
COOH & \\
COOH & \\
\hline
COOH & \\
C$$

# (iii) From nitriles and amides

Alkyl cyanides on hydrolysis with dilute acids or alkalies give carboxylic acids.

$$\begin{array}{c} \text{CH}_3 - \text{CN} + 2\text{H}_2\text{O} \xrightarrow{\hspace{1cm} \text{Dil.HCl}} \text{CH}_3 - \text{COOH} + \hspace{1cm} \text{NH}_4\text{Cl} \\ \text{Methyl cyanide} \end{array}$$
 
$$\begin{array}{c} \text{CH}_3 - \text{CONH}_2 + \text{H}_2\text{O} \xrightarrow{\hspace{1cm} \text{H}^+ \\ \text{heat}} \end{array} \rightarrow \begin{array}{c} \text{CH}_3 - \text{COOH} + \hspace{1cm} \text{NH}_3 \end{array}$$

## (iv) From Grignard reagents

Grignard reagents when treated with carbon dioxide give carboxylic acids.

CH<sub>3</sub> = Mg Br + CO<sub>2</sub> 
$$\xrightarrow{\text{Dry ether}}$$
 CH<sub>3</sub> =  $\overset{\text{O}}{\text{C}}$  = O Mg Br  $\xrightarrow{\text{H}_2\text{O}/\text{H}^+}$  CH<sub>3</sub> = COOH + Mg  $\xrightarrow{\text{Prom alkenes}}$  Br

Alkenes are oxidized to acids by oxidizing agents like chromic acid or acidic or alk.  $KMnO_4$  or acidic  $K_2Cr_2O_7$ 

$$R - CH = CH - R \xrightarrow{K_2Cr_2O_7} R - COOH$$

$$\xrightarrow{KMnO_4} \xrightarrow{H_2SO_4} COOH$$

# (vi) From acid halides, anhydrides and esters

Acid halides give carboxylic acids when hydrolysed with water. They are more readily hydrolysed with aqueous base to give carboxylate ions. This on acidification give acids..

$$\begin{array}{ccc}
R - C - CI & & & & & & & \\
II & & & & & & \\
O & & & & & & \\
\end{array}$$

$$\begin{array}{cccc}
H_2O & & & & & \\
R - COOH + CI^- & & & \\
OH^-/H_2O & & & & \\
\end{array}$$

$$\begin{array}{cccc}
R - COO^- + CI^- & & & \\
H_3O^+ & & & \\
\end{array}$$

$$\begin{array}{cccc}
R - COOH + CI^- & & & \\
\end{array}$$

Anhydrides are hydrolysed by water to give acids

$$C_6H_5-CO-O-CO-CH_3+H_2O\longrightarrow C_6H_5-COOH+CH_3-COOH$$

Benzoicacid Ethanoic acid

Acidic hydrolysis of esters directly give acids. But basic hydrolysis give carboxylates which on acidification give acids.

$$COOC_2H_5 \xrightarrow{H_2O^+} COOH + C_2H_5OH$$

$$CH_3 - CH_2 - CH_2 - COOC_2H_5 \xrightarrow{NaOH} CH_3 - CH_2 - CH_2 - COONa + C_2H_5OH$$

$$H_3O^+ CH_3 - CH_2 - CH_2 - COOH$$
Butanoic acid

# Physical Properties

The first three aliphatic acids are colourless liquids with pungent smell. The next six are oily liquids. The higher members are colourless, odourless waxy solids. Benzoic acid is a crystalline solid.

### Solubility:

They are soluble in water due to inter-molecular hydrogen bonding with water molecules. With increase in size of the alkyl group, solubility decreases. Higher members are practically insoluble in water.

## **Boiling Point**

Carboxylic acids have higher boiling points than aldehydes, ketones and even alcohols of comparable molecular masses. This is due to the presence of intermolecular hydrogen bonding. Due to hydrogen bonding carboxylic acid exists as a dimmer. The hydrogen bonds are not broken completely even in the vapour phase.

$$R-C$$

$$0 - H - O$$

$$0 - H - O$$

$$\delta + \delta - O$$

The O– H bond in carboxylic acids is more polar than O– H bond in alcohols. This is due to electron withdrawing effect of carbonyl group on O– H. Hence hydrogen bonding in carboxylic acids are more stronger than those in alcohols.

Due to dimeric structure the effective molecular mass of the acid becomes double the actual mass. This is evident from its colligative properties

The melting points and boiling points of aromatic acids are usually higher than those of aliphatic acids of comparable molecular mass.

### **Chemical Properties**

#### I. Acidic nature

Carboxylic acids are the most acidic amongst the organic compounds. However, they are less acidic than mineral acids ( $H_2SO_4$ , HCI,  $HNO_3$  etc)

Carboxylic acids are acidic due to the presence of polar O– H group. In aqueous solution, it ionizes to give carboxylate anion and the hydronium ion.

$$R - COOH + H_2O \implies R - COO^- + H_3O^+$$

The carboxylate ions are stabilized by resonance.

$$R - C \bigcirc \longrightarrow R - C \bigcirc = R - C \bigcirc (-)$$

At equilibrium, the equilirium constant Ka is expressed as

$$Ka = \frac{[R - COO^{-}][H_3O^{+}]}{[R - COOH]}$$

The equilibrium constant ka is called *acidity or dissociation constant*. Larger the value of Ka, the stronger is the acid. But it is more convenient to express the acidic strength in terms of its pKa value (pKa = -log Ka). Now, smaller the value of pKa, stronger is the acid.

### Carboxylic acids are more acidic than phenols. Why?

The conjugate base of carboxylic acid (carboxylate ion) is stabilized by two equivalent resonance structures. Here the negative charge is at the more electronegative oxygen atom. But the conjugate base of phenol (phenoxide ion) has non equivalent resonance structures. Moreover the negative charge is at the less electronegative carbon atom.

### Effect of substituents on acidic strength

The substituents present on the aliphatic chain or aromatic ring affect the acidity of carboxylic acids.

The electron withdrawing groups stabilize the carboxylate ion by dispersal of the negative charge. Hence they increase the strength of the acid.

The electron releasing groups cause concentration of negative charge and thus destabilize the carboxylate anion. Hence they decrease the strength of the acid.

Electron withdrawing groups like halo group, —NO<sub>2</sub>, —CN etc increase the acidity. Electron donating groups like alkyl groups decrease the acidity of carboxylic acids.

# (i) H – COOH is more acidic than CH₃ – COOH

$$H-C O CH_3 \rightarrow C O - H$$

In acetic acid the electron donating effect (+I effect) of the methyl group destabilizes the anion. Hence it is weaker acid than formic acid.

## (ii) $CH_3 - COOH < CICH_2 - COOH < CI_2CH - COOH < CI_3C - COOH$

The acidic strength increase from acetic acid to trichloro acetic acid. Compared to the acetate ion, the electron withdrawing chlorine atom in chloro acetate ion tends to decrease the electron density over carboxylate ion. Hence chloroacetate ion is more stabilized.

$$CH_3$$
  $C$   $CI$   $CH_2$   $C$   $O$ 

Acetate ion (less stable) Chloroacetate ion (stable)

The increase in number of chlorine atoms increases the acidity of the acid.

(iii) 
$$CH_3 - \overset{\alpha}{C}H - COOH > \overset{\beta}{C}H_2 - CH_2 - COOH CI CI$$

The effect of substituent decreases as its distance from the —COOH group increases.

### (iv) The effect of electron withdrawing is different for different halogens

Hence the acidic strength of the acids increases in the order.

$$ICH_2 - COOH < BrCH_2 - COOH < CICH_2 - COOH < FCH_2 - COOH$$

### Acid strength of substituted benzoic acids

Electron withdrawing groups like -CI,  $-NO_2$ , etc increase the acidic strength. The electron releasing groups such as  $-CH_3$ ,  $-NH_2$  etc decrease the acidic strength.

The effect is more pronounced at para position as compared to that at meta position.

## The order of acidic strength

 $CF_3COOH > CCI_3COOH > CHCI_2COOH > NO_2CH_2COOH > NC-CH_2COOH > FCH_2COOH > CICH_2COOH > BrCH_2COOH > HCOOH > CICH_2CH_2COOH > C_6H_5COOH > C_6H_5COOH > CH_3COOH > CH_3COOH$ 

The attachment of phenyl or vinyl group to carboxylic acid increases the acidity of carboxylic acids. This is because of greater electronegativity of sp<sup>2</sup> hybridised carbon. (But this is against the decrease expected due to resonance effect shown below.)

$$CH_2 = C \qquad C \qquad \longleftrightarrow \qquad C \qquad H_2 - C = C \qquad OH \qquad OH$$

### 1. Reaction with metals

Carboxylic acids react with metals such as Na, K, Zn etc and liberate hydrogen gas.

$$2 \text{ CH}_3 - \text{COOH} + \text{Zn} \rightarrow (\text{CH}_3 - \text{COO})_2 \text{Zn} + \text{H}_2$$

#### 2. Reaction with alkalies

Carboxylic acids react with alkalies (NaOH, KOH) to form salt and water.

$$CH_3 - COOH + NaOH \rightarrow CH_3 - COONa + H_2O$$

# 3. Reaction with bicarbonate (Test for true acids)

$$R - COOH + NaHCO_3 \rightarrow R - COONa + CO_2 + H_2O$$

#### 4. Reaction with ammonia

Carboxylic acids react with ammonia to form ammonium salts which on heating gives amides

$$CH_{3}-COOH+NH_{3} \xrightarrow{C} CH_{3}-COONH_{4} \xrightarrow{\Delta} CH_{3}-CONH_{2} + H_{2}O$$

$$COOH \xrightarrow{COO} NH_{4}^{+} \xrightarrow{\Delta} CONH_{2}$$

$$+ NH_{3} \xrightarrow{C} COONH_{4}^{+} \xrightarrow{\Delta} CONH_{2}$$

$$COOH \xrightarrow{COO} NH_{4}^{+} \xrightarrow{A} CONH_{2}$$

$$COOH \xrightarrow{COO} NH_{4}^{+} \xrightarrow{A} CONH_{2}$$

# II. Reduction

Phthalmide

Lithium aluminium hydride can reduce carboxylic acids to primary alcohols

$$CH_3 - COOH + LiAlH_4 / diborane(B_2H_6) \rightarrow CH_3 - CH_2 - OH$$

Carboxylic acids can be reduced to alkanes on reaction with HI in the presence of phosphorus at 500K.

$$CH_3 - COOH + 6 HI \xrightarrow{P} CH_3 - CH_3 + 2H_2O + 3I_2$$

But NaBH4 (Sodium borohydride) does not reduce the carboxylic acid.

## Decarboxylation

## (i) Sodalime decarboxylation.

Sodium or potassium salts of carboxylic acids on heating with soda-lime (NaOH and CaO) give alkanes with one carbon less than the parent acids.

$$CH_3 - COONa + NaOH \xrightarrow{CaO} CH_4 + Na_2CO_3$$

When two carboxyl groups are attached to the same carbon atom, decarboxylation takes place by simple heating.

COOH
$$CH_2 \xrightarrow{COOH} CH_2 \xrightarrow{415-435K} CH_2 - COOH + CO_2$$
Malonic acid acetic acid

(ii) Calcium salts of carboxylic acids on heating gives aldehydes and ketones.

$$(CH_3 - COO)_2Ca \xrightarrow{Heat} CH_3 - CO - CH_3 + CaCO_3$$

# (iii) Kolbe's electrolysis:

Aqueous solutions of sodium or potassium salts of carboxylic acids on electrolysis give alkanes at anode. This reaction is called Kolbes's electrolysis.

$$CH_3 - COONa_{(aq)} \rightarrow CH_3 - COO^- + Na^+$$

At Anode: 
$$CH_3 - COO^- \rightarrow CH_3 - CH_3 + 2CO_2 + 2e^-$$

At cathode: 
$$2H_2O + 2e^- \rightarrow H_2 + 2OH^-$$

# HVZ- Reaction [Hell - Volhard - Zelinsky Reaction]

When carboxylic acids are treated with  $Cl_2$  or  $Br_2$  in the presence of red phosphorus, the  $\alpha$ -hydrogen atoms of carboxylic acids are replaced by chlorine or bromine. This reaction continues till all the  $\alpha$ -hydrogens are replaced

$$CH_3-COOH \xrightarrow{\quad Cl_2/P \quad} CH_2CI-COOH \xrightarrow{\quad Cl_2/P \quad} CHCl_2-COOH \xrightarrow{\quad Cl_2/P \quad} CCl_3-COOH$$

This reaction has great synthetic importance as the halogen atom can be replaced by a number other groups giving useful products.

### Reaction with PCI<sub>5</sub>, PCI<sub>3</sub> and SOCI<sub>2</sub>

Acids can be readily converted to acid chlorides by the action of thionyl chloride, PCI3 or PCI5.

$$\begin{array}{lll} R-COOH + PCI_5 & \rightarrow & R-CO-CI + POCI_3 + HCI \\ 3 \ R-COOH + PCI_3 & \rightarrow & 3 \ R-COCI + H_3PO_3 \\ R-COOH + SOCI_2 & \rightarrow & R-COCI + SO_2 + HCI \end{array}$$

### Formation of anhydride

Carboxylic acids on heating with mineral acids such as  $H_2SO_4$  or  $P_2O_5$  give corresponding acid anhydrides.

### Esterification

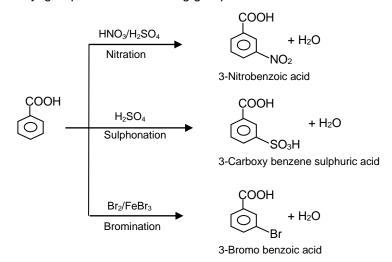

Carboxylic acids are esterified with alcohols or phenols in the presence of a mineral acid such as concentrated H<sub>2</sub>SO<sub>4</sub> or HCl as catalyst.

$$R-COOH + R'-OH \stackrel{H^+}{\rightleftharpoons} R-COOR' + H_2O$$

### Mechanism: Esterification is a kind of nucleophilic acyl substitution

# Ring substitution in aromatic acids

Carboxyl group is a meta directing group since it is electron withdrawing.

# **Vinegar**

3-7% solution of CH<sub>3</sub> – COOH is called <u>vinegar</u>. It is obtained by the fermentation of ethyl alcohol by the bacteria '*acetobacter*'.

$$\begin{array}{c} \operatorname{CH_3} - \operatorname{CH_2} - \operatorname{OH} + \operatorname{O_2} \xrightarrow{\quad \text{Acetobacte r} \quad} & \operatorname{CH_3} - \operatorname{COOH} + \operatorname{H_2O} \\ & \operatorname{Ethyl \ alcohol} & \operatorname{Aceticacid} \end{array}$$

#### Uses of acids:

Formic acid is used in rubber, leather and electroplating industries.

**Acetic acid** is used in the manufacture of rayon and in plastic, rubber and silk industries. It also finds use as a solvent. Vinegar is used in cooking.

**Benzoic acid** Esters of benzoic acid are used in perfume industry. The salts of benzoic acid such as **sodium benzoate** are used as food preservatives. 1,2– Benzene dicarboxylic acid (Phthalic acid) is used in the manufacture of plasticisers and resins.1,4 – Benzene dicarboxylic acid (terephthalic acid) is the raw material for polyester production.

# Glacial acetic acid

Water free acetic acid obtained by melting of the crystals is called glacial acetic acid.
